Cohort Acronym

NLSY79

Cohort type

General population-based cohort

Disease

Participant type

No diagnosis

Profile

Recruitment Period 1979

Sample size at start or planned sample size if still recruiting

Estimated Current Sample Size

Age at Recruitment 14-22

Gender Male and Female

Abstract

The NLSY 1979 Cohort is a longitudinal project that follows the lives of 12,686 American youth born between 1957 and 1964. The study was intended to be representative of United States residents, both male and female. It observes the life-course experiences of young adults who were finishing their schooling and were making decisions about education and training, entering the labour market, military service, marriage, and having families. Cohort members are now in their 50s and survey content has turned to age-appropriate topics including health and retirement expectations.

Yearly personal interviews were conducted from 1979 – 1986. In 1987, a telephone interview was conducted. Personal interviews resumed in 1988 and continued yearly until 1994. Since 1994, NLSY79 participants have been interviewed in even-numbered years.

Funders (Core support) National Longitudinal Surveys – U.S Bureau of Labour Statistics

Variables Collected

Brain related measures:

N/A

Functional rating:

Individual psychological

Anthropometric:

Blood pressure, Height, Weight

Physical:

Cardiovascular, Hearing and Vision, Reproductive, Respiratory

Biological samples:

N/A

Genotyping:

N/A

Brain imaging:

N/A

Brain banking:

N/A

Lifestyle:

Alcohol, Dietary habits, Physical activity, Smoking

Socio-economic:

Education, Ethnic group, Family circumstances, Housing and accommodation, Income and finances, Marital status, Occupation and employment

Health service utilisation:

N/A
