Research Abstract

Patients with advanced Parkinson's disease often have rapid swings between mobility and immobility, and many respond unsatisfactorily to adjustments in pharmacological treatment. We assessed whether globus pallidus pars interna (GPI) deep brain stimulation (DBS) gives greater functional improvement than does subthalamic nucleus (STN) DBS. Although there was no difference in our primary outcomes, our findings suggest that STN could be the preferred target

for DBS in patients with advanced Parkinson's disease.
